ABSTRACT

The paper presents an overview of agent-based multisimulation applications in management simulation games. The scenario-based game management concept is introduced in the paper. Agent-directed multi-simulation framework for management simulation games is developed. An illustrative example for a specific web-based logistic simulation game is provided.

Keywords: multisimulation, multi-models, agent-based simulation, agent-supported simulation

1. INTRODUCTION

Computer simulation games are widely used in management education to provide extensive experience under control conditions. In general, they are contrived situation which imbed players in a simulated business environment, where they make management-type decisions from time to time, and their choices at one time generally affect the environmental conditions under which the subsequent decisions must be made. In other words the main purpose of management simulation game is to simulate interactions between business actors, so they are well suited for using agent-directed approaches. Multisimulation is a novel simulation methodology allowing simultaneous explorations of different simulation scenarios which plays very important role within the structure of simulation games.

Agent-directed simulation that integrates agent and simulation paradigms has two distinct categories (Ören, 2000; Yilmaz, 2005; Yilmaz and Ören, 2006): (a) use of simulation for agents or agent simulation, and (b) use of agents for simulation (agent-supported simulation and agent-based simulation). Agent simulation, i.e., simulation of agent systems is used in several application areas: manufacturing systems, robotics, transportation, logistics, e-commerce, etc. Agent-supported simulation involves the use of intelligent agents to improve simulation and gaming infrastructures and environment. Agent-based simulation is the use of agent technology to generate or monitor model behavior in a simulation study. In this study, in addition of agent simulation, agent-supported and agent-based simulation is used for the development of management games.

2. AGENTS IN TUTORING SYSTEMS

Agent technology is widely used in different tutoring systems. For, example, in (Hospers et al., 2003) such an agent-based system for nurse education is discussed. Here authors describe the development of an effective teaching environment called Ines or Intelligent Nursing Education Software that uses agents to support learning and is able to provide sensitive feedback, demonstrations of practical exercises and/or explanations. Two architecture styles are used in Ines: (1) "data abstraction and object-oriented organization," and (2) "event based, implicit invocation." The first one means that single components are represented by objects that have their own attributes and methods. Objects could be identified as physical objects used by nurse in practice (needles, swaps, etc) and agents used in learning process. Objects are implemented by using several classes within Java. The second architecture style is used to implement agents’ behaviour in the tutoring system. Each agent is capable of transmitting messages to other agents, and receiving messages by observing all messages that are sent to that agent or that are broadcasted to all agents.

Ines architecture consists of four main parts: input from devices, a concrete user interface, an abstract user interface and the cognitive part which includes student, instructions, domain, and patient models. Two types of software agents, i.e. proactive and reactive agents, are used in the instruction model to provide teaching instructions to a nursing student. Each proactive agent observes the user interface and send an observation to a reactive agent. Reactive agents receive the observations...
and respond to them. The following are examples of proactive (a) and reactive (b) agents that define their function, i.e., (a) Time Agent, Error Agent, Task Observer and Sterile Agent, and (b) Feedback Agent, Interaction Observer Agent and Examination Agent. To implement agents, the agent platform developed by the Parlevink group is used.

Capuano et al. (2000) present an innovative architecture for Agent Based Intelligent Tutoring System (ABITS) by using the Multi-Agent paradigm. ABITS extends a traditional Course Management System (CMS) with a set of intelligent functions which allow student modeling and automatic curriculum generation and aimed to improve the learning effectiveness based on the adaptation of the teaching material to student skills and preferences. ABITS knowledge indexing is based metadata about the learning objects and their interrelations, and conceptual graph that is used to link concepts underlying the knowledge domain, i.e., prerequisite, sub-concept, and so on. To implement a multi-agent paradigm in ABITS, Java-based Agent framework JAFMAS is used. ABITS implements three main types of agents, one for each base function topology. Evaluation Agents function is evaluating and updating the Cognitive state that contains the knowledge degree, reached by a particular student. Affective Agents perform evaluating and updating Learning Preferences that enclose information about the student perceptive capabilities. And Pedagogical Agents perform evaluating and updating Course Curriculum depending on learning goals, cognitive states and learning preferences. Additionally, to ensure communication between CMS and ABITS, Spooler Agent is embedded in the CMS module. When CMS requires an ABITS service, it requests this service to the Spooler Agent which requests services from Evaluation, Affective or Pedagogical agents as needed. The main innovative issues of ABITS system are based on adoption of software agents and distributed nature of the software architecture.

3. AGENTS IN MANAGEMENT GAMES

The literature review provides several examples of agents’ functions in management games. For instance, in Van Luin et al. (2004), the classic supply chain simulation and management game called, as the Beer Game, is remodelled as a multi-agent based simulation using the Agent-Object-Relationship (AOR) modelling language. Authors extend and refine the classical discrete event simulation paradigm by enriching it with the basic concepts of the AOR metamodel. The resulting simulation method is called as Agent-Object-Relationship Simulation (AORS). In AOR modelling language, an entity is an agent, an event, an action, a claim, a commitment, or an ordinary object. Agents can communicate, perceive, act, make commitments and satisfy claims while objects are passive entities without such capabilities. The state of AORS system contains the simulated time, the environment state including the non-agentive environment (as a collection of objects) and the external states of all agents (e.g., their physical state, their geographic position, etc.), the internal agent states (e.g., representing perceptions, beliefs, memory, goals, etc.), and a list of future events. At the Beer Game four agents with similar behavior can be identified: the retailer, wholesaler, distributor and factory. Each agent receives orders from the downstream supply chain node and delivers from its upstream node. Here, the incoming and outgoing orders are modelled as messages, the shipping of beer as a non-communicative action event and the reception of beer is modelled as non-action event. The reactions of agents to the incoming events are specified in the form of production type rules. For instance, the rule that is triggered periodically at the end of week (event) compares the current inventory with outstanding orders and either send the entire order or ship the maximum available quantity of beer. AORS model of the Beer Game have been used for testing different replenishment policies in supply chains, however authors did not consider how a supply chain agent could improve its performance by learning from the game past experience.

Overviews of agent based paradigms and enterprise simulation for e-learning and knowledge transmission is given by Remondino (2007, 2008). Author discusses the integration of cognitive and reactive agents to web based business games. Cognitive agents’ behaviour is goal-directed and reason-based, so they may have different roles in the game, for instance, the agent can compute some strategies to be used to make profit in the simulation. That said, this agent could then be used both as a decision support system for human users – since it could foresee some results, based on its acquired experience – and as a virtual tutor, explaining the relations among certain variables (decisions) and the achieved results. Reinforcement learning algorithms are used to evaluate utility of action to take next. Reactive agents simply retrieve preset behaviours. From a structural point of view, the reactive agents can constitute some parts of the model itself, in order to make it self-adaptive when facing unforeseen decisions and context (simulate customer or supplier, represent production plants, etc.). Evolutionary algorithms (for example, Genetic Algorithm) may be applied for reactive agents to solve action selection problem.

Dobson et al. (2004) investigated technologies, which may have significant impact on the business game-based training and as the most promising the agent technology is considered. Several possible functions of an agent in the business strategy game are proposed: (1) representing market entity, sometimes completely replacing a human player or working in the background as an individual assistant to the learner; (2) monitoring trainee and evaluating his/her actions online; (3) modeling consumers’ behavior. Authors successfully implemented agent technology in strategy business game for the telecommunication industry. The developed game provides the assistance for learners via agents and the
following advantages are found: agents demonstrate optimal behavior by making rational decisions that offers a range of new opportunities for competency development in the trainees; the ability of the rule-based systems to provide the logics leading to decisions made by the agents for the human player allow the trainee to learn from these explanations in the process of the game; if necessary, the agent-based game can be run at much faster pace that offers an opportunity to run multiple scenarios in just one class session and in such way to investigate the impact of various parameters on the business and industry as a whole. However, all suggestions made by authors have declarative nature so more information is needed on particular models and agent realization.

The development of a simulation game, REAL Business, using an agent-based approach is described by Bai et al. (2007). The proposed architecture extends the traditional ICAI (Intelligent Computer Aided Instruction) architecture, which utilize the techniques of expert systems and artificial intelligence to help a person learn interactively and consists of expert module, pedagogical module, and user model. REAL contains the following components: (1) reflective agent which stores specific information about individual learners (e.g., level of competence) to be used by the pedagogical agent, (2) expert agent which contains expert knowledge of a particular subject domain (e.g., in REAL Business, the domain knowledge is on probability and in REAL Plant - ecology), (3) pedagogical agent which compares the knowledge of an expert agent with the reflective agent and thus provides teaching strategies (for instance, for those who showed competence within the first business community, the agent may generate situations where some resources are limited), and (4) communication agent controls the human computer interaction, it observes the user’s mouse click and provides users with help for using tools; clarifies learning goals; gives navigation orientations, etc. In REAL business, Students are supposed to help a store owner design business strategies to run an ice cream store. They taught a reflective agent through observing the event network, probabilities to multiple events, as well as data from the prior sales and design production rules. The outcome is observed in the simulation game by making rational decisions that offers a range of new opportunities for competency development in the trainees; the ability of the rule-based systems to provide the logics leading to decisions made by the agents for the human player allow the trainee to learn from these explanations in the process of the game; if necessary, the agent-based game can be run at much faster pace that offers an opportunity to run multiple scenarios in just one class session and in such way to investigate the impact of various parameters on the business and industry as a whole. However, all suggestions made by authors have declarative nature so more information is needed on particular models and agent realization.

The game simulation could be performed according to a predefined scenario chosen (or specially elaborated) by the game manager. Scenario plays very important role within the game structure and it has to be formalized for further agent implementation.

In general, a scenario can be conceived as a means of transforming the system's initial state to a final state, following main development trends, which are influenced by both internal events and external activities. It could be presented by the following 5-tuple:

<SI, T, E, A, SF>,

where:

- SI presents initial state of the system;
- T presents predefined system development trends (e.g., demand process);
- E presents predefined internal events (e.g., changes in demand process);
- A presents performed external activities (e.g., number of produced items);
- SF defines results or the system final state once the scenario has terminated.

The generic scenario structure is shown below (see Figure 1).
Patterns of these trends depend on the type of function and its parameters.

All internal and external influences depend on the current system state and they are aimed at achieving particular result of the system functioning. Any internal and external influences lead to short-term or long-term changes in the pattern of trends, i.e.

\[ f_i^E : E \rightarrow T_i \quad \text{and} \quad f_i^A : A \rightarrow T_i , \]

where \( E = \{ e_1, e_2, \ldots, e_n \} \) is a set of internal events; and \( A = \{ a_1, a_2, \ldots, a_n \} \) is a set of external activities.

System initial state is defined by the system structure as well as by value of the trends’ functions at the moment when the system investigation starts:

\[ SI = T_i(t_0) , \]

where \( t_0 \) defines the initial time instant.

In terms of management simulation game, scenario specifies the initial state of game’s business environment and determines the development of the game situation through time according to predefined trends as well as contains the list of important events taking place during simulation. Events are indicated by the game manager and can affect trends. Participants make their decisions (or in other words, take actions) that can affect both trends and events. Trends may be configured according to the teaching goals by changing appropriate parameters available in the game.

### 4.2. Roles of Intelligent Agents

Intelligent agents can be introduced in the game in different ways (see Figure 3): (a) agents may perform tasks of the game manager related to the elaboration of the game scenario and control the game session, (b) play a participant role, (c) and perform a tutor function in the game.

#### 4.3. Agent-supported Game Manager

An agent can perform tasks of the game manager (see Figure 4) related to the elaboration of the game scenario, i.e., to define and set initial conditions of the game according to a composed story or developed case study, monitoring the game session by checking trends and defining events, and making necessary changes in scenario during run-time by modifying trend functions, i.e.

```plaintext
set SI
for each j
    for each i
        define \( T_i(t_j) \)
        generate \( e_i \in E \)
        if \( e_i \neq \emptyset \)
            modify \( T_i(t_{j+1}) \)
end
end
```

It is well-known from experience that the human factor significantly can create inconsistencies in the designed scenario which, with a high probability, may lead to serious mistakes in the game. Agents would have the capability to increase the consistency, completeness and other qualities of the game scenario and the reliability of its software. Production rules embedded in the game software. Production rules embedded in the game.
software can be used to set up parameters of the business environment according to defined policies. In order to generate production rules, inductive learning algorithms can be used. Monitoring of the game scenario is based on the dynamic comparison of parameters of the business environment and state of the companies in the game.

4.4. Agent as a Virtual Player and/or a Tutor

If a business game of this type is used for individual training, the agent could substitute another competitive company and be introduced to simulate its behaviour, i.e. in the above algorithm, which describes behaviour of the Scenario Manager Agent, instead of event $e_i$, activity $a_i$ is introduced. The structural scheme of an agent-based simulator is given in Figure 5.

5. MULTISIMULATION FOR GAME SCENARIOS

In general, multisimulation is a simulation, where at decision points, simulation updated may include decisions on branching of simulation studies as well as selection of models/submodels and associated parameters and experimental conditions to be analysed simultaneously and used in subsequent stage of simulation (Yilmaz et al., 2006). Therefore, from the above definition we can presume that multisimulation concept could be successfully applied for management of simulation games. Multisimulation methodology is introduced to enable exploratory simulation using various types of multimodels. A multimodel consists of several submodels where only one or some of them is/are active at a given time. The “multimodel” formalism introduced by Ören (1987, 1991) can be applied to specify scenarios.

5.1. Scenario Multimodel

Most of scenario management functions are described above. One of them is monitoring of the game session, and making necessary scenario alternations during runtime. Monitoring is aimed at managing key indicators of functioning of business environment. If any of indicators is out of critical value then the necessary changes should be introduced to the current scenario or, in other words, the alternative scenario should be applied that allow changing current situation according to the training goals. A multimodel is associated with a dynamic scenario that defines the sequence of scenarios in specific time moments (see, Figure 7), where $S_i$ is the initial scenario in the game, but $S_1$, ..., $S_n$ – possible alternative scenarios, $S_1$, ..., $S_{m_1}$ and $S_n$, ..., $S_{n_k}$ – respective subsequent scenarios.

The corresponding scheme of Tutor Agent and Trainee interactions is presented in Figure 6.
does not allow structural changes) and adaptive behaviour are introduced. In the last case constraint-driven multimodels are controlled by stationary or adaptive transitions policies that can have learning capabilities. Therefore, the task of alternative scenario choosing can be delegated to the agent.

5.2. Agent-Supported Scenario Multisimulation

Choosing the alternative scenario requires computational support to (1) observe simulation state, (2) reason to qualify scenario for update, and (3) plan for constraint-driven activation by exploring potential paths within the state space of the problem domain. Each sub-scenario is viewed as an operator that transforms the state of the simulation model. Agent paradigm provides the necessary computational infrastructure to attain these objectives.

The scenario manager agent decouples the simulator of the game logic from scenario models and it is aimed at performing dynamic scenario updates. The activation conditions of submodels are defined in terms of production system. A hypothetical submodel activation process is shown in Figure 8.

![Figure 8: Submodel Activation Process](image)

The input to the process refers to the observed condition used by the compare submodels component. Dynamic submodel replacement requires monitoring simulation conditions to determine if any of the potential state variables of interest are changed and it could be an indicator of a scenario update in the simulator. During the model comparison phase all submodels, the preconditions of which are implied by the current observed state are identified and their comparison is performed by the scenario manager agent. During the next phase only one submodel should be qualified for further exploration. Finally, simulator of the game logic is updated by the selected submodel.

6. AN ILLUSTRATIVE EXAMPLE

As an example of a management simulation game for introducing agent-directed multisimulation technology, the International Logistics Management Game (ILMG) is selected (Grubbström et al. 2005). The game is aimed at providing virtual business environment for training decision-making skills in the area of international logistics, production management, finances, etc. The game can be classified as a total enterprise (or general management), interacting, computer-aided and internet-based, real-time processed business simulation. ILMG software functioning according the structure presented in Figure 2.

Different scenarios in the game are introduced to simulate real world situations and force trainees to acquire skills and experience in managing different functions of the company in various situations. During the game, participants operate as different corporations within international market, producing goods or services (i.e. making strategic and operational decisions) and competing each other in order to improve their corporation performance and to achieve the following goals: earn profit, capture substantial market share, and achieve high customer satisfaction.

The ILMG scenario is generated by the game manager according to the needs of a specific training goal and the participants’ knowledge background. The business environment and the MIS reports are made as complex as in a real life or it could be simplified as necessary. Initial conditions of the game and corporations’ state are set up by changing different parameters that can be divided to several groups (see, Figure 9): regional parameters (e.g., unit projecting cost, basic wage level), regional-related production parameters (e.g., productivity parameters, overheads parameters), technical coefficients of products (e.g., material per unit, setup cost), market related parameters (e.g., price effect parameters), financial parameters (e.g., prime rate, tax rate), etc.

Most of the parameters have to be defined before the game starts and they can’t be changed afterwards. However some parameters (i.e., prime rate, business cycle index of the region, regional productivity index, and regional wage level) can be easily edited during the game that allows changing business environment to simulate different situations.

![Figure 9: Scenario Elaboration Screen](image)
The game manager decides only about number of regions and products as well as their characteristics; then the software generates all other parameters automatically. Regions have three possible characteristics: with (1) advanced, (2) less advanced and (3) developing economy. Products can be (1) hi-tech, (2) "medium"-tech and (3) low-tech. The following algorithm is proposed for the automatic generation of parameters:

- The full range of parameters’ values is defined;
- Each of defined range is divided in three equal subsets;
- Each of parameters’ subset characterizes either one of region type: (1) advanced, (2) less advanced and (3) developing economy, or product type: be (1) hi-tech, (2) "medium"-tech and (3) low-tech;
- Within each subset values of parameters are generated randomly.

Further, the game is used to simulate generated scenario and to display the results. Here the procedure of dynamic scenario update is not yet explored.

7. CONCLUSIONS

An agent-directed multisimulation framework for scenario simulation in management simulation games is proposed in the paper. Three possible roles for agents in games are considered: scenario manager, virtual player, and virtual tutor. Though, the use of agents in simulation in general and in simulation games in particular is widespread, however combination of multisimulation with agent technology is a novel concept that seems to be very promising for use in simulation games, especially for scenario management in interacting, computer-aided and internet-based, real-time processed business simulations. The example of such game is considered in the final chapter of the paper.
